An analog modeling synthesizer is a synthesizer that generates the sounds of traditional analog synthesizers using DSP components and software algorithms. Analog modeling synthesizers simulate the behavior of the original electric and electronic circuitry in order to digitally replicate their tone.

and returns the signed result in the analog domain (differentially). The sum (or average, as discussed below) of  $N_{\text{mult}}$  of these outputs is then passed to a differential analog-to-digital converter (ADC), which converts the analog dot product back to the digital domain with some effective number of bits of information (ENOBVMAC).

Simulating mixed-signal circuit designs needs to bridge between the analog and digital circuit domains. Preserving the behavior and structure of the analog and digital parts of the circuit is possible with Hardware Description Languages (HDLs), such as Verilog-AMS. However, the analog and digital parts of the design are typically developed in simulation environments tailored to either the analog or digital design flow requirements.
